#### Introduction to Linear Models

STA721 Linear Models Duke University

Merlise Clyde

August 25, 2015

#### Coordinates

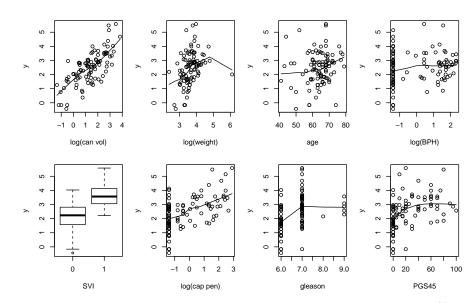

- Instructor: Merlise Clyde 214 Old Chemistry Office Hours MWF 1:00-2:0 or right after class (or by appointment)
- ► Teaching Assistants: Nicole Dalzell & Shin Shirota
- Course: Theory and Application of linear models from both a frequentist (classical) and Bayesian perspective
- Prerequisites: linear algebra and a mathematical statistics course covering likelihoods and distribution theory (normal, t, F, chi-square, gamma distributions)
- Introduce R programming as needed
- Introduce Bayesian methods, but assume that you are co-registered in 601 or have taken it previously
- more info on Course Website
  http://stat.duke.edu/courses/Fall15/sta721

#### Introduction

Build "regression" models that relate a response variable to a collection of covariates

- Goals of Analysis?
  - Predictive models
  - Causal interpretation
  - Testing of hypotheses
  - confirmatory or validation analyses
- Observational versus Experimental data? (Confounding)
- Sampling Schemes Generalizibility
- Statistical Theory

# Prostate Example

## Simple Linear Regression

#### Simple Linear Regression:

$$y_i = \beta_0 + \beta_1 x_i + \epsilon_i$$
 for  $i = 1, \dots, n$ 

Rewrite in vectors:

$$\begin{bmatrix} y_1 \\ \vdots \\ y_n \end{bmatrix} = \begin{bmatrix} 1 \\ \vdots \\ 1 \end{bmatrix} \beta_0 + \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix} \beta_1 + \begin{bmatrix} \epsilon_1 \\ \vdots \\ \epsilon_n \end{bmatrix}$$

$$\begin{bmatrix} y_1 \\ \vdots \\ y_n \end{bmatrix} = \begin{bmatrix} 1 & x_1 \\ \vdots & \vdots \\ 1 & x_n \end{bmatrix} \begin{bmatrix} \beta_0 \\ \beta_1 \end{bmatrix} + \begin{bmatrix} \epsilon_1 \\ \vdots \\ \epsilon_n \end{bmatrix}$$

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

## Multiple Regression

$$y_i = \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + \dots \beta_p x_{pi} + \epsilon_i$$

Design matrix

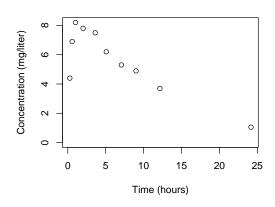

$$\mathbf{X} = \begin{array}{cccc} 1 & x_{11} & \dots & x_{p1} \\ 1 & x_{12} & \dots & x_{p2} \\ \vdots & \vdots & \vdots & \vdots \\ 1 & x_{1n} & \dots & x_{pn} \end{array}$$
$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \epsilon$$

what should go into **X** and do we need all columns of **X** for inference about **Y**?

#### Nonlinear Models

Mean function may be an intrinsically nonlinear function of t

$$\mathsf{E}[Y_i] = f(t_i, \boldsymbol{\theta})$$

### Quadratic Linear Regression

Taylor's Theorem:

$$f(t_i, \theta) = f(t_0, \theta) + (t_i - t_0)f'(t_0, \theta) + (t_i - t_0)^2 \frac{f''(t_0, \theta)}{2} + R(t_i, \theta)$$

$$y_i = \beta_0 + \beta_1 x_i + \beta_2 x_i^2 + \epsilon_i \text{ for } i = 1, ..., n$$

Rewrite in vectors:

$$\begin{bmatrix} y_1 \\ \vdots \\ y_n \end{bmatrix} = \begin{bmatrix} 1 & x_1 & x_1^2 \\ \vdots & \vdots & \\ 1 & x_n & x_n^2 \end{bmatrix} \begin{bmatrix} \beta_0 \\ \beta_1 \\ \beta_2 \end{bmatrix} + \begin{bmatrix} \epsilon_1 \\ \vdots \\ \epsilon_n \end{bmatrix}$$

 $\mathbf{Y} = \mathbf{X}oldsymbol{eta} + oldsymbol{\epsilon}$ 

Quadratic in x, but linear in  $\beta$ 's, but remainder term is in errors  $\epsilon$ 

duke.eps

# Polynomial Linear Regression

Polynomial Regression:

$$y_i = \sum_{j=0}^q \beta_j x_i^j + \epsilon_i \text{ for } i = 1, \dots, n$$

Rewrite in vector notation:

$$\begin{bmatrix} y_1 \\ \vdots \\ y_n \end{bmatrix} = \begin{bmatrix} 1 & x_1 & x_1^2 & \dots & x_1^q \\ \vdots & \vdots & & & \\ 1 & x_n & x_n^2 & \dots & x_n^q \end{bmatrix} \begin{bmatrix} \beta_0 \\ \beta_1 \\ \beta_2 \\ \vdots \\ \beta_q \end{bmatrix} + \begin{bmatrix} \epsilon_1 \\ \vdots \\ \epsilon_n \end{bmatrix}$$

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

How large should q be? Use Nonlinear Regression or other Nonparametric models

# Kernel Regression

Kernel Regression:

$$y_i = eta_0 + \sum_{j=1}^J eta_j e^{-\lambda (\mathsf{x}_i - k_j)^d} + \epsilon_i ext{ for } i = 1, \dots, n$$

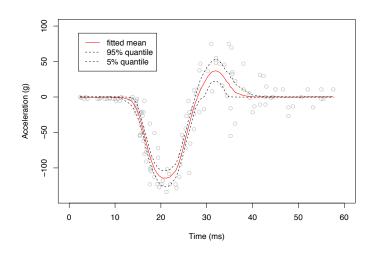

where  $k_j$  are kernel locations and  $\lambda$  is a smoothing parameter

$$\begin{bmatrix} y_1 \\ \vdots \\ y_n \end{bmatrix} = \begin{bmatrix} 1 & e^{-\lambda(x_1 - k_1)^d} & \dots & e^{-\lambda(x_1 - k_J)^d} \\ \vdots & \vdots & & \vdots \\ 1 & e^{-\lambda(x_n - k_1)^d} & \dots & e^{-\lambda(x_n - k_J)^d} \end{bmatrix} \begin{bmatrix} \beta_0 \\ \beta_1 \\ \vdots \\ \beta_J \end{bmatrix} + \begin{bmatrix} \epsilon_1 \\ \vdots \\ \epsilon_n \end{bmatrix}$$

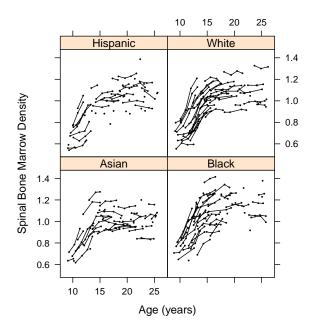

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

Linear in 
$$\beta$$
 given  $\lambda$   
Learn  $\lambda$  and  $J$ 

## Kernel Regression Example

### Hierarchical Models - Spinal Bone Density

#### Generic Linear Model

Generic Model in Matrix Notation is

$$\mathbf{Y} = \mathbf{X} \boldsymbol{\beta} + \boldsymbol{\epsilon}$$

- **Y**  $(n \times 1)$  vector of response (observe)
- $ightharpoonup X (n \times p)$  design matrix (observe)
- ▶  $\beta$  ( $p \times 1$ ) vector of coefficients (unknown)
- ullet  $\epsilon$  (n imes 1) vector of "errors" (unobservable)

#### Goals:

- ▶ What goes into **X**? (model building and model selection)
- What if several models are equally good? (model averaging)
- What about the future? (Prediction)
- lacktriangle uncertainty quantification assumptions about  $\epsilon$

All models are wrong, but some may be useful (George Box)

### **Ordinary Least Squares**

Goal: Find the best fitting "line" or "hyper-plane" that minimizes

$$\sum_{i} (Y_i - \mathbf{x}_i^T \boldsymbol{\beta})^2 = (\mathbf{Y} - \mathbf{X} \boldsymbol{\beta})^T (\mathbf{Y} - \mathbf{X} \boldsymbol{\beta}) = \|\mathbf{Y} - \mathbf{X} \boldsymbol{\beta}\|^2$$

- Optimization problem
- May over-fit ⇒ add other criteria that provide a penalty "Penalized Least Squares"
- ▶ Robustness to extreme points ⇒ replace quadratic loss with other functions
- no notion of uncertainty of estimates
- no structure of problem (repeated measures on individual, randomization restrictions, etc)

Need Distribution Assumptions of Y (or  $\epsilon$ ) for testing and uncertainty measures  $\Rightarrow$  Likelihood and Bayesian inference

## Philosophy

- for many problems frequentist and Bayesian methods will give similar answers (more a matter of taste in interpretation)
- ► For small problems, Bayesian methods allow us to incorporate prior information which provides better calibrated answers
- for problems with complex designs and/or missing data
   Bayesian methods are often easier to implement (do not need to rely on asymptotics)
- For problems involving hypothesis testing or model selection frequentist and Bayesian methods can be strikingly different.
- Frequentist methods often faster (particularly with "big data") so great for exploratory analysis and for building a "data-sense"
- Bayesian methods sit on top of Frequentist Likelihood

Important to understand advantages and problems of each perspective!
